Summary:

Experimental research has been conducted in order to establish the new quantum key distribution system for secure and undecipherable quantum communications. The system has been based on optical single-photon transmitters and superconducting single-photon detector receivers. The photon transmitters were based on heavily attenuated femtosecond optical pulses, generated by a high-repetition-rate laser. Novel superconducting devices were designed and developed for efficient and ultrafast counting of visible-light and near-infrared (telecommunication wavelength) photons. The photon counters were operated in the quantum detection mode, based on photon-induced hotspot formation and subsequent appearance of a transient resistive barrier across an ultrathin and submicron-width superconducting stripe. The devices were fabricated as nanostructured NbN interdigitated serpentine lines with the nominal active area $10 \times 10 \mu\text{m}^2$ and operated at cryogenic (liquid helium) temperatures inside a cryostat. The detector experimental quantum efficiency in the photon-counting mode reached above 10% in the visible range of radiation and up to 8% at the 1.3- to 1.55- μm range. The dark counts were below 0.1 per second. The measured real-time counting rate was above 2 GHz and jitter was below 18 ps, both limited by our readout electronics. In terms of the photon-counting efficiency, speed, and jitter, our NbN superconducting single-photon detectors are significantly better than any competing semiconductor avalanche photodiodes and photomultipliers.

Objectives:

The objective of this research effort was to establish the new quantum key distribution (QKD) communication system, based on optical single-photon transmitters (Quantum Alice) and receivers (Quantum Bob). The program brought together UR and IF AFRL researchers to achieve the development of both fiber-optic and free-space high-speed QED prototype systems. The objective of this project were achieved through realization of 4 separate tasks, aimed to:

- develop superconducting single-photon counters, integrated into the “Quantum Bob” receivers for Gb/s digital clock rates for secure quantum communication;
- establish jitter-free fast-laser transmitter (Quantum Alice) with single-picosecond pulses carrying on average one photon per pulse and characterized by the repetition rate ranging from 100 MHz to 3 GHz;
- perform simulations and computer characterization of the quantum communication channel in the QKD system, including impact of privacy amplification and authentication, and signal propagation in lossy (e.g., Earth atmosphere) media (This task was led by IF AFRL.);
- establish a comprehensive subpicosecond and nanoscale characterization facility at the University of Rochester for testing and characterization of quantum information transmitter/receiver devices and quantum computation systems. Train and educate a new generation of scientists in the area of quantum information electronics and photonics.

Realization of Objectives:

All objectives set in the research goal of this grant have been reached. In particular, we have developed novel superconducting single-photon detectors (SSPDs) for ultrafast counting of the visible-light and near-infrared photons for secure quantum communications and quantum cryptography. Our devices consist of nanostructured NbN interdigitated serpentine lines, have the nominal active area $10 \times 10 \mu\text{m}^2$ and operate at 4.2 K, well below the NbN superconducting transition temperature. The SSPDs operate in the quantum detection mode, based on photon-induced hotspot formation and subsequent appearance of a transient resistive barrier across an ultrathin and submicron-width superconducting stripe. Our best devices achieve experimental quantum efficiency (QE) from >10% for 405-nm radiation to ~5% for 1550-nm photons, real-time counting rate of >2 GHz, jitter <18 ps, and dark counts <0.1 per second. In terms of the photon-counting speed and jitter, our SSPDs significantly outperform semiconductor avalanche photodiodes and photomultipliers.

We have also established our Ultrafast Quantum Phenomena Laboratory for testing quantum information transmitter/receiver (Alice/Bob) devices. We performed extensive characterization of our photodetectors both in terms of QE and the speed of response. Our measurements were performed in the simulated Alice-Bob scenario in the photon wavelengths ranging from visible light to near infrared (telecommunication).

Accomplishments/New Finding:

Ultrafast digital data processing and "unlimited" bandwidth communication, including quantum computing and quantum information, are the most crucial elements for the Air Force future missions and warfare.

- (1) We experimentally demonstrated unique advantages of our detectors for ultrafast quantum key distribution and communications. The experimental QE of our NbN SSPDs in the photon-counting mode reached above 10% in the visible range of radiation and up to 8% at the 1.3- to 1.55- μm near-infrared range. The dark counts were below 0.1 per second and the noise-equivalent power (NEP) was $2 \times 10^{-17} \text{ W/Hz}^{1/2}$ at 1.3 μm —the record low value for any near-infrared photon counters. See publications: [1], [4], and [9].
- (2) We have studied time-resolved dynamics of the resistive-state formation in 10-nm-thick, 130-nm-wide NbN superconducting stripes exposed to single photons and observed a $65(\pm 5)$ -ps time delay in the switching onset. The time-delay phenomenon has been explained within the framework of a model based on photon-induced generation of a hotspot in the superconducting stripe. The measured time delays in both the single-photon and two-photon detection regimes agree well with theoretical predictions of the resistive-state dynamics in quasi-one-dimensional superconducting stripes. Fluctuations of the time-delay values have been identified as the source of jitter, measured in our SSPDs. See publications: [2], [5], [10], and [11].
- (3) We have tested our SSPDs specially designed for near-infrared quantum communications and quantum key distribution (Quantum Bob). The measurements were performed using a Pritel fiber-mode-locked laser (Quantum Alice), which generated a train of 1.6-ps-wide optical pulses with the telecommunication wavelength of 1.55 μm . The Pritel laser variable repetition rate ranged from 1 GHz to 3 GHz. Real-time counting of 1.55 μm photons was performed. The actual measured counting rate was up to 2 GHz and was limited by our readout electronics (the intrinsic response time is below 30 ps). The SSPD jitter was below 18 ps, the lowest value reported for any photon detectors. See publications: [3], [7], [8], and [13].
- (4) Our SSPDs have been implemented in a VLSI CMOS integrated circuit testing system, based on the detection of time-resolved, near-infrared photon emission from switching transistors. The system was commercialized by NPTest Inc., the leader in advanced tools for VLSI microchips debugging in the semiconducting industry. The patent protection for the SSPD was filed in the US Patent Office. We also received the 2003 *R&D Magazine* Award for one of the 100 most innovative products developed worldwide in 2003. See publications: [6], [14], and [15].

(5) In direct collaboration with the Moscow State Pedagogical University in Russia, we have developed advanced technology for fabrication of nanostructured SSPDs. With the help of AFRL/SNDD and their focused ion beam (FIB) tool, we have begun to define the SSPD stripe width to the scale of the film thickness (4 nm). The initial sample fabrication, demonstrated the exquisite process control, however, the sample was not superconducting. We attempted to refine the dimensional and fabrication constraints to obtain operational devices, unfortunately, the FIB process poisoned the NbN thin film and resulted in nonsuperconducting meander stripes.
See publications: [12] and [16].

(6) We established Ultrafast Quantum Phenomena Laboratory at the University of Rochester. The Ultrafast Lab is dedicated to basic and applied research on ultrafast phenomena in solids and on novel materials, devices, and testing technologies for optoelectronic quantum information systems. This is an interdisciplinary effort, which combines condensed matter physics and quantum electrodynamics with optics, nanoelectronics, and cryogenics.

See website: <http://www.ece.rochester.edu/projects/ufqp/index.html>

Table below summarizes our in the SSPD development supported by this grant, by directly comparing the SSPD performance with other advanced, semiconductor single-photon devices and with the W transition edge sensor (bolometer) developed at NIST, Boulder, CO. The comparison has been done for the telecommunication wavelength 1.3 μm . We see that in terms overall performance our SSPDs significantly outperform any currently available competing technologies for single photon counting.

PERFORMANCE OF DIFFERENT SINGLE-PHOTON DETECTORS OPERATING AT $\lambda = 1.3 \mu\text{m}$

Detector Model	Counting rate (Hz)	QE (%)	Jitter (ps)	Dark Counts (s ⁻¹)	NEP (W/Hz ^{1/2})
InGaAs PFD5W1KS APD (Fujitsu)	5×10^6	>20	>200	6×10^3	3×10^{-17}
R5509-43 PMT (Hamamatsu)	9×10^6	1	150	1.6×10^4	$\sim 10^{-16}$
Si APD SPCM-AQR- 16 (EG&G)	5×10^6	0.01	350	25	$\sim 10^{-16}$
W bolometer- 0.1 K (NIST)	2×10^4	>90	N/A	$<10^{-4}$	$<10^{-19}$
SSPD - 4.2 K	2×10^9	8	<18	<0.1	2×10^{-17}

Personnel Supported:

Professor Roman Sobolewski, PI – part-time summer
Dr. Aleksandr Verevkin, Scientist – part-time
Dr. Wojciech Slys, Visiting Scientist – part-time
Mr. Aaron Pearlman, graduate student
Mr. Jin Zhang, graduate student
Ms. Jennifer Kitaygorodskaya, graduate student
Mr. Daozhi Wang, graduate student

Completed Ph. D. Thesis
